

THE SCHOOL'S DAILY OPERATING SYSTEM

The software that runs the school day — and writes it down for you.

An AI-native operating system for schools: it plans the whole academic year down to the period, captures every class in a single tap, turns it into per-student growth, and reports the day back to you — while adapting to how your school actually works.

A school runs on its days. We make every day visible.

Most school software digitises paperwork. TrackBit runs the operating loop of the school itself — the plan, the timetable, the classroom, the child, the parent, and the money — from a single source of truth that the staff never have to stop and feed. The data enters itself, as a byproduct of teaching. That is why it is still in use in March, when the binders and the half-filled apps have been abandoned.

Schools don't fail on strategy. They fail on the days.

A school is a promise made 200 times a day, one period at a time. Whether that promise is kept — the class taught, the syllabus paced, the weak student caught, the parent informed — is almost impossible for a principal to actually see. The result is a school run on faith and hindsight.

The director is flying blind. What they know about today is a monthly summary, written after the fact and often reverse-engineered to look fine. Were all eight periods held? Is the syllabus actually on pace? They find out a class is eight chapters behind a week before the exam — when nothing can be done.

The teacher has no minute to spare. The same attendance and homework get written into a register, a diary, and a WhatsApp group. Any system that asks them to mark a 40-student class one by one is dead on arrival, so the data is

never captured cleanly, and nothing downstream can be trusted.

The parent is the last to know. A call to the office, and still no clear answer about their child's day — what was taught, what homework was set, what was missed while the child was absent.

And the tools they bought died by March. Every one demanded data entry nobody had time for. The information lives scattered across Excel and WhatsApp, none of it connected, none of it queryable, no single source of truth.

The gap is never the plan. It is the distance between the plan and what actually happened — and no one can see across it in time to act.

Capture by exception: confirm the norm, log only what changed.

Every hard problem above comes down to one thing — getting clean, daily ground truth without adding work. TrackBit's answer is a single mechanism that runs through the whole product: the teacher confirms the normal case in one tap, and records only the deviations.

Attendance is "**all present**," minus the few you tap. The daily plan is "**we did the lesson**," minus what **didn't get done**. A period goes on the record in four taps, under thirty seconds. Because the teacher gets value the instant they give data — homework logged is homework the parent already sees — the loop sustains itself. From that one honest tap, everything else is **computed, not entered**: per-student growth, syllabus pace, the parent's view, the director's dashboard, and the report that writes itself.

01

Compile the year

Syllabus, staff and roster become a plan for every class-subject, down to the period.

02

Confirm by exception

Teachers tap the norm and log only deviations — who was away, what didn't get done.

03

Join into truth

Timetable × attendance × topics × homework × scores, computed per student.

04

Report & act

The 8 AM report surfaces risks; each gap becomes a task in one tap.

THE PLATFORM AT A GLANCE

CORE Academic Planner Year plan to the period, held to the classroom log.	CORE Timetable Teacher schedules, clash-checked and live.	CORE Classroom & Attendance Per-period capture in a single tap.
CORE Homework Set once; the parent sees it instantly.	CORE Parent Portal A login into the child's real day.	CORE Exams & Growth Scores in, growth tracked subject by subject.
CORE Daily Report The day, written for the director by 8 AM.	LAYER Tasks & Boards The school's other work, tracked and claimable.	LAYER Fees Structures, receipts and a trustworthy ledger.
LAYER Hostel & Sessions Evening prep and activities, same rails.	INTELLIGENCE Lucy — agentic AI Ask the school anything, in plain language.	INTELLIGENCE Generative UI Describe a view; the system builds it.

One loop, ten ways it pays off.

Each module below stands on its own, but every one reads from and writes to the same daily truth — so nothing is ever entered twice, and every screen agrees with every other.

03 · ACADEMIC PLANNER & TRACKER

The whole year, planned down to the period — and held to it.

You give TrackBit the syllabus and the school calendar; it compiles a period-by-period plan for every class-subject, aware of terms, holidays and real teaching days. Chapters are sized against the actual periods available, so an over-ambitious portion is flagged before the year starts, not after.

Then it holds the school to that plan. The approved plan is the **baseline**; the classroom log is the **actual**. A live red / amber / green forecast shows exactly which class-subjects are on pace and which are slipping — and an exam-fit check answers the question that matters: *can this portion still be finished before the test?*

Mid-year adoption

04 · TIMETABLE

Every teacher's week, mapped, clash-checked, and live.

The timetable maps periods to classes and teachers, with a deterministic clash detector that refuses to double-book a teacher. Import it from a photo or a spreadsheet and the system reads it in; from that grid, each teacher's day assembles itself into the list of periods they'll actually teach.

It is effective-dated and append-only, so a mid-term change to the schedule never rewrites history — last month's records still reflect the timetable that was truly in force then.

Photo / spreadsheet import

Teacher clash detection

Effective-dated changes

What happened in every classroom, captured in a single tap.

This is where capture by exception earns its keep. A teacher opens the period, taps "all present" and marks the few absentees, picks the topic from the syllabus list, and sets homework — the whole period, on the record, in seconds. An optional deep log lets the teacher flag only the students who stood out, never the whole class.

The first attendance of the day quietly triggers what the school needs it to — the record a parent will later see, the absence a class teacher should follow up. Nobody fills a register twice.

One-tap "all present"

Topic from the plan

Exception-only deep log

"Not held" reasons

Homework that reaches the parent the moment it's set.

Homework is logged as part of closing the period — class-wide, or for specific students when the work is personal. Because it lands in the same system the parent can see, the teacher gets value the instant they record it: the parent is informed without a single extra message being written.

Replaces: the homework diary, the class WhatsApp group, and the "my child forgot to write it down" phone call.

Parents stop calling the office. They log in and see the day.

Every parent gets a login to their child's actual day: the topic taught in each period, the homework set, and — when their child was absent — exactly which topics they missed, so the gap can be closed at home. It is the class record, in the open, and it turns the school's daily capture into the parent's transparency at no extra effort.

What parents see is the record of the class and their child's part in it. The private intervention tiers that staff use to target help are **never** shown to a parent — transparency where it builds trust, discretion where it protects the child.

Per-period topics

Homework set

Missed-while-absent

Performance over time

Every child's growth, subject by subject, on one screen.

Enter exam results — by typing, or by dropping a photo of the marks sheet, which the system reads and pre-fills for review. Those scores flow into a growth view for every child: how much of each subject has actually been taught, the topics they missed while absent, their test trend over time, a skill profile, and the areas where they need help.

Behind the scenes, staff can group students into private A/B/C support tiers and spin up targeted interventions that become trackable tasks — the mechanism that turns "this child is slipping" into something the school actually does.

[Photo marks-sheet capture](#)[Per-subject growth](#)[Skill profile & trend](#)[Private support tiers](#)[Interventions → tasks](#)

Nobody writes the report. It writes itself by 8 AM.

Overnight, TrackBit reads the whole day — attendance, topics covered, homework, syllabus pace, sessions and fees — and composes the report a principal would otherwise spend an hour assembling: the risks that need attention, the loose ends and ambiguities, and the wins worth celebrating. It is on the director's phone before the first bell.

Replaces: the Monday review deck, the WhatsApp round-up, and the hours spent chasing staff for numbers.

The school's other work — on boards anyone can pick up.

Sitting on top of the academic core is a full task layer for everything else a school runs on: maintenance, housekeeping, events, admin. Work can be assigned to a person or left claimable on a public board; recurring routines materialise themselves. Crucially, every alert on the director's dashboard becomes a task in one tap — so a red syllabus forecast or a repeat absentee doesn't just get noticed, it gets owned.

[Assign or claim](#)[Recurring routines](#)[Alert → task in one tap](#)[Full audit trail](#)

Fees you can trust — and a day that doesn't end at the last bell.

The fee module handles structures, instalment plans, discounts and receipts on an append-only ledger — every payment, undo and adjustment is a new entry, never a silent edit, so the books can always be trusted. Fees are director-only; teachers never see a rupee.

For residential schools, the hostel runs on the same rails as the school day: evening prep, study blocks and activities, with rosters that compute themselves from class and boarder status. The child's day is tracked from the first bell to lights-out, in one continuous record.

Not a chatbot bolted on. A system that rebuilds itself around you.

Most "AI in edtech" is a chat window stapled to the side of an old product. TrackBit's AI is the opposite: it reaches into the live school through the same permissions a human has, and it can compose the interface itself. This is the part of the product with no equivalent in the market — and the reason a school that adopts TrackBit keeps discovering new value long after go-live.

— THE ADAPTIVE SCHOOL OS

Ask it. And watch it build.

Underneath sits a registry of the school's real capabilities — every service the product exposes, described in a machine-readable way. The AI plans over those capabilities to answer a question or take an action, and then *renders the answer as live interface*: a table, a chart, a roster, a report card — chosen and assembled on the spot from real data it is not allowed to invent.

SHIPPED · AGENTIC ASSISTANT

Lucy — ask your school anything.

"Which classes are behind on Science before the half-yearly?" Lucy reads the live plan and answers with a real, data-backed view — through the asker's own permissions, so a teacher sees their classes and a director sees the school. Anything that changes data waits for a human's confirmation.

GENERATIVE UI

Describe a view; it appears.

The interface is not a fixed set of screens. The AI materialises the right view from the data on demand — the numbers are always server-computed and never typed by the model. The system shows you what you asked to see, built in the moment.

describe → *plan over capabilities* → *act (with confirm)* → *generate the interface* The same registry that powers this today is the seed of tomorrow: as the capability set grows, so does what can be described into being — from a new view, toward a new module.

A school that describes what it wants to track, and watches the module take shape. That is the direction we are building — a school operating system that reshapes itself to how each school actually works.

Everywhere else in the product, the same doctrine holds: **AI proposes, a human confirms, and deterministic rules decide**. It drafts the year plan, splits a chapter into teachable topics, reads a timetable photo, and writes the daily report — but every output lands in a review surface a person signs off before anything is saved. The intelligence makes the work effortless without ever putting the school on autopilot.

Why it survives past March, when other tools are abandoned.

The reason isn't a feature — it's the shape of the whole system. Value comes before data entry, and data entry is never a separate job.

Teachers give the least, and get the most. The only thing asked of a teacher is a few taps per period — and even that pays them back immediately, because logging homework informs the parent and closing a period clears their list. There is no data-entry role to hire, no clerk transcribing registers, no month-end scramble.

Everyone downstream reads one truth. The parent's portal, the director's dashboard, the growth tracker and the daily report are all *views* of the same captured day. Nothing is stored twice, so nothing can disagree. Fix a fact once and every screen updates.

It meets the school where it is. A school can adopt TrackBit mid-year, size chapters as each term begins, and run two campuses or a hostel — the system bends to that instead of demanding the year start over. Onboarding is done *for* the school, from the files it already has.

And it compounds. Every day of capture makes the growth history richer, the forecasts sharper, and the AI's answers more grounded. The product a school uses in year two is measurably more valuable than the one they started with — without a single upgrade to buy.

Built so the data can be trusted — and the private stays private.

Tenant isolation, enforced at the database.

Every school's data is scoped by a verified identity on every request and fenced by row-level security in the database itself — so a query can never reach across schools, even by mistake. Multi-school operation is a first-class design, not a bolt-on.

Append-only history — undo, never overwrite.

Fees, plan approvals, band changes and score verifications are recorded as new entries, not silent edits. An undo is a compensating entry. The books and the record can always be audited, and nothing quietly disappears.

Bands are private by design.

The A/B/C support tiers exist only to target help. They are staff-only and, as a hard product rule, never appear on any parent-facing surface. Discretion is enforced in the architecture, not left to policy.

AI that can't fabricate.

The assistant renders only server-computed data, and any action it proposes is a confirmable pending step, not a silent write. The model chooses how to present the truth; it is structurally prevented from inventing it.

A simple model: one price, per student.

No editions, no add-ons, no free tier to configure and abandon. The school pays, and TrackBit builds their school inside the product from the files they already have — and hands it over working.

₹100 per student · per month

MINIMUM 500 STUDENTS PER SCHOOL

Billed on the active roll. A 800-student school runs at ₹80,000 / month — a fraction of a single administrator's cost, for the school's entire operating system.

EVERY PLAN INCLUDES

- ✓ Every module — no tiers
- ✓ Full setup done by us, from your files
- ✓ Syllabus, roster & staff import
- ✓ Timetable built and validated
- ✓ Plans generated and approved with you
- ✓ Staff training and handover
- ✓ Unlimited teacher & admin accounts
- ✓ A parent login for every family

Who it's for: established schools of 500 students and up — day schools, residential schools and multi-campus groups — that are ready to run on real daily data instead of month-end paperwork. The floor is deliberate: below it, the hands-on setup and support that make TrackBit stick don't pencil out.

The school operating system that keeps growing.

TrackBit today already runs the daily loop of the school — plan, classroom, child, parent, money — from one source of truth. The trajectory is to make that operating system *adaptive*: a platform where a school describes a new thing it wants to track and the system composes it, where the AI moves from answering questions to assembling whole modules, and where every additional school and every additional day makes the intelligence sharper for everyone.

The moat is not any one feature — competitors can copy a screen. It is the combination that is hard to assemble: a capture mechanism teachers actually sustain, a single connected truth underneath, and an AI layer that can reshape the product itself. That combination is what turns software a school merely buys into the system a school runs on.

See it on your own school.

The most convincing demo isn't a sample school — it's yours. We load a slice of your real classes, subjects and calendar, and show you the day board, the parent portal and the report that writes itself.
